Objective

The objective of this monograph is to provide producers and users of death statistics with a practical tool to help study deaths related to accidental poisonings.

Methods

Mortality data produced by health authorities of 33 European countries and compiled yearly by Eurostat were used. Depending on their availability, data were used to describe time trends, geographical distributions and demographical risks.

By reviewing the literature, the international forum for mortality specialists, the revision and update process of the International Classification of Diseases (ICD) and the answers of a questionnaire filled in by death statistics producers of 36 European countries in the framework of the ANAMORT project, it has been possible to:

- describe the limits of the observed differences
- elaborate recommendations for a better use of available data
- elaborate recommendations for a better production of future data.

Definition of deaths related to poisoning

Death from accidental poisoning was considered as any death reported to Eurostat, with an underlying cause of death coded X40 to X49 (table 1) in the 10th revision of ICD (ICD-10).

Death from poisoning was considered as any death due to poisoning, whatever the intent was; in addition to death from accidental poisoning, it included suicide by poisoning, homicide by poisoning, poisoning from undetermined intent, and death from contact with venomous animals and plants.

Definition of indicators used

The number of deaths for each group of underlying causes of death (UCOd) was the one transmitted by the countries’ national authorities to Eurostat for a given year. Aggregation of the number of deaths for the European Union (EU) was made by Eurostat, using the last available data for a given year. Crude death rate (CDR) was obtained by dividing the number of deaths by the last estimate of the population available in Eurostat (for a given age group if age specific crude death rate was computed). Age-standardised death rate (SDR) was computed by direct standardisation, using the 1976 European population. The potential years of life lost before 75 years-old (PYLL75) due to a given cause were calculated for each age group by multiplying the number of deaths related to this cause by the difference between age 75 and the mean age at death in each age group. Potential years of life lost were the sum of the products obtained for each age group. Proportions of PYLL75 were calculated by dividing the PYLL75 due to a given cause by the total amount of PYLL75 due to all causes of death. Indicators were produced at country level, for all countries of EU15 or EU25. For other groups of countries, estimation of a given indicator was calculated as an average of this indicator at country level weighed by the proportion of its population among the group.

Situation regarding deaths from poisoning in Europe

The number of deaths from accidental poisoning in EU25 was 10,194 in 2005, which represents 4.4% of deaths due to external causes. SDR for accidental poisoning was 2.1 for 100,000 inhabitants in 2005, among the 25 countries of the European Union. Variations between 0.2 and 20.0/100,000/year according to the countries were observed in Europe (Figure 1).

1. Included the 25 Member States of the European Union before 2007, Albania, Bulgaria, Croatia, Iceland, Macedonia, Norway, Romania and Switzerland.
2. epp.eurostat.ec.europa.eu.
3. www.nordclass.uu.se/index_e.htm.
4. 33 above mentioned countries, Bosnia Herzegovina, Serbia and Turkey.
6. EU15 comprised the following 15 countries: Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, the Netherlands, Portugal, Spain, Sweden, and the United Kingdom.
7. EU25 comprised EU15 and the following 10 countries: Cyprus, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Malta, Poland, Slovak Republic, and Slovenia.
The highest risks of death from accidental poisoning were observed in north-eastern countries (Lithuania, Estonia, Latvia, Finland, Norway and Poland).

The risk of death by accidental poisoning was 3.1 times higher among men (average for EU25 in 2005). This difference was particularly important between ages 20 and 69 years (Figure 2). In 2005 among EU25 countries, victims were observed among the elderly (65 years-old and more) in 24% of the cases. The highest CDRs were observed among people between 30 and 59 years-old (maximum for the 45-49 years-old age group with 3.8/100,000 in 2005).

There was no clear trend regarding the SDR between 2000 and 2005 in the EU25 and between 1994 and 2005 in the EU15 (Figure 3). In certain countries, a sharp decrease in SDR by accidental poisoning could be observed (Switzerland 1995, Greece 1995) or inversely, a noticeable increase (+44% in France in 2000, +190% in Norway in 2003). Some of these decreases or increases were associated with the implementation of the 10th revision of ICD as in France and Switzerland. The 10 new Member States, mostly in Eastern Europe, explained the increase in death rates by accidental poisoning in the European Union (EU25 versus EU15) was due to higher incidence rates in these countries (Figure 3).

In 22 countries, it was possible to obtain statistics on “all poisonings” (whatever the intent was, see table 1) in 2005. Non-accidental poisonings represented 0 to 92% of all poisonings (40% on average for all these countries).

8. Austria, Croatia, Cyprus, Czech Republic, Estonia, Metropolitan France, Greece, Hungary, Iceland, Ireland, Latvia, Lithuania, Macedonia (the former Republic of Yugoslav) Malta, Norway, Poland, Romania, Slovakia, Slovenia, Spain, Sweden, and Switzerland.
In EU25, deaths from accidental poisoning were responsible for 6% of the PYLL by external causes of death. The highest impact was among people between 20 and 49 years of age (Figure 4).

Interpretation and limitations of observed differences in deaths by poisoning in Europe

Increased rates of death related to accidental poisoning in northern and eastern European countries had been attributed to acute poisoning by alcohol.

Misclassifications of deaths from accidental poisoning due to inappropriate selection of underlying causes of death were described by 22 out of the 36 countries questioned during the Anamort project. The combined effect of these misclassifications was considered to lead to understimation of the magnitude of the deaths due to accidental poisonings in most of these countries.

Lack of investigation and low rates of autopsy can have an impact on underestimation of cases of accidental poisoning. These cases would therefore be coded as mental and behavioural disorders due to psychoactive substance use (ICD-10 codes: F10-F19), suicides or poisoning with undetermined intent.

On the opposite, overestimation of deaths by accidental poisoning might be observed when the intent is not clearly reported.

Analytical recommendation to improve comparability of time trends (for statistics users)

Time trends regarding deaths coded X40-X49 (Accidental poisoning) and F10-F19 (Mental and behavioural disorders due to psychoactive substance use) should be monitored in order to study misclassifications between these two groups.

In order to have an overview of mortality related to poisoning, it would be interesting to analyse deaths due to overdose considering all possible categories: accidental, suicides, homicides, undetermined intent also including the F codes related to drugs in the analyses.

To better identify poisoning-related cases, other tools could be used such as:
- multiple cause of death analyses in order to identify drug use including in particular some T and F codes
- textual analyses in order to identify specific illegal substances.

Recommendations to improve comparability of future data collected (for data producers)

Coders should always request the results of toxicological analyses for deaths due to poisoning if data on agents/substances are not provided.

Cases of overdose-related deaths should be coded both with the underlying cause of death (i.e. X or Y codes) as well as with T codes identifying the drugs involved (i.e. X42 and T40).

Deaths coded as cardiac arrest or unspecified cause of death in younger age groups (below 45) should be specifically analysed because there could be some external causes of death, and more particularly accidental poisoning cases.

Additional and more detailed recommendations may be found on www.invs.sante.fr/surveillance/anamort.
